

HomeLink Device

This device collects information from the GPS API and sends a radio signal to the garage door to open the door or close it whenever it's within reach. This device operates on a radio frequency, the circuit acts as a toggle switch that toggles a "change state" whenever a button is pressed. The GPS activates a button option once the car is within range of the home and once the user presses the button, the state is toggled from close to open.
